### Data Structures

- class **CachedConsumer**  
*A cached message consumer contained within a pooled session.*
- class **CachedProducer**  
*A cached message producer contained within a pooled session.*
- class **CmsAccessor**  
*Base class for `activemq.cmsutil.CmsTemplate` (p. 1170) and other CMS-accessing gateway helpers, defining common properties such as the CMS `cms.ConnectionFactory` (p. 1324) to operate on.*
- class **CmsDestinationAccessor**  
*Extends the `CmsAccessor` (p. 1153) to add support for resolving destination names.*
- class **CmsTemplate**  
*`CmsTemplate` (p. 1170) simplifies performing synchronous CMS operations.*
- class **DestinationResolver**  
*Resolves a CMS destination name to a `Destination`.*
- class **DynamicDestinationResolver**  
*Resolves a CMS destination name to a `Destination`.*
- class **MessageCreator**  
*Creates the user-defined message to be sent by the `CmsTemplate` (p. 1170).*
- class **PooledSession**  
*A pooled session object that wraps around a delegate session.*
- class **ProducerCallback**  
*Callback for sending a message to a CMS destination.*
- class **ResourceLifecycleManager**

### 6.1.1 Detailed Description

**template<typename E> class decaf::util::AbstractCollection< E >**

This class provides a skeletal implementation of the **Collection** (p. 1184) interface, to minimize the effort required to implement this interface. To implement an unmodifiable collection, the programmer needs only to extend this class and provide implementations for the iterator and size methods. (The iterator returned by the iterator method must implement hasNext and next.)

To implement a modifiable collection, the programmer must additionally override this class's add method (which otherwise throws an UnsupportedOperationException), and the iterator returned by the iterator method must additionally implement its remove method.

The programmer should generally provide a void (no argument) and **Collection** (p. 1184) constructor, as per the recommendation in the **Collection** (p. 1184) interface specification.

The documentation for each non-abstract method in this class describes its implementation in detail. Each of these methods may be overridden if the collection being implemented admits a more efficient implementation.

E >::add (const E &value DECAF_UNUSED) throw  
( lang::exceptions::UnsupportedOperationException,  
lang::exceptions::IllegalArgumentException,  
lang::exceptions::IllegalStateException ) [inline,  
virtual]`

Ensures that this collection contains the specified element (optional operation). Returns true if this collection changed as a result of the call. (Returns false if this collection does not permit duplicates and already contains the specified element.)

Collections that support this operation may place limitations on what elements may be added to this collection. **Collection** (p. 1184) classes should clearly specify in their documentation any restrictions on what elements may be added.

If a collection refuses to add a particular element for any reason other than that it already contains the element, it must throw an exception (rather than returning false). This preserves the invariant that a collection always contains the specified element after this call returns.

This implementation always throws an `UnsupportedOperationException`.

### Parameters:

*value* - The element that must be ensured to be in this collection.

### Returns:

true if the collection was changed as a result of this call.

### Exceptions:

***UnsupportedOperationException*** if the add operation is not supported by this collection

***IllegalArgumentException*** if some property of the element prevents it from being added to this collection

***IllegalStateException*** if the element cannot be added at this time due to insertion restrictions

```

6.1.3.2  template<typename E> virtual bool decaf::util::AbstractCollection<
        E >::addAll (const Collection< E > & collection) throw
        ( lang::exceptions::UnsupportedOperationException,
        lang::exceptions::IllegalArgumentException,
        lang::exceptions::IllegalStateException ) [inline,
        virtual]

```

Adds all of the elements in the specified collection to this collection (optional operation). The behavior of this operation is undefined if the specified collection is modified while the operation is in progress. (This implies that the behavior of this call is undefined if the specified collection is this collection, and this collection is nonempty.)

This implementation iterates over the specified collection, and adds each object returned by the iterator to this collection, in turn.

Note that this implementation will throw an `UnsupportedOperationException` unless `add` is overridden (assuming the specified collection is non-empty).

#### Parameters:

*collection* - The **Collection** (p.1184) whose elements are to be added to this **Collection** (p.1184).

#### Returns:

true if the collection was changed as a result of this call.

#### Exceptions:

*UnsupportedOperationException* if the `addAll` operation is not supported by this collection

*IllegalArgumentException* if some property of the element prevents it from being added to this collection

*IllegalStateException* if the element cannot be added at this time due to insertion restrictions

Reimplemented in `decaf::util::AbstractQueue< E >` (p.195).

```

6.1.3.3  template<typename E> virtual void decaf::util::AbstractCollection< E
        >::clear () throw ( lang::exceptions::UnsupportedOperationException )
        [inline, virtual]

```

Removes all of the elements from this collection (optional operation). The collection will be empty after this method returns.

This implementation iterates over this collection, removing each element using the **Iterator.remove** (p.2155) operation. Most implementations will probably choose to override this method for efficiency.

Note that this implementation will throw an `UnsupportedOperationException` if the iterator returned by this collection's iterator method does not implement the `remove` method and this collection is non-empty.

#### Exceptions:

*UnsupportedOperationException* if the `clear` operation is not supported by this collection

**6.1.3.13** `template<typename E> virtual bool decaf::util::AbstractCollection< E >::remove (const E & value) throw ( lang::exceptions::UnsupportedOperationException, lang::exceptions::IllegalArgumentException ) [inline, virtual]`

Removes a single instance of the specified element from this collection, if it is present (optional operation). More formally, removes the first element *e* such that *e* == *o*, if this collection contains one or more such elements. Returns true if this collection contained the specified element (or equivalently, if this collection changed as a result of the call).

This implementation iterates over the collection looking for the specified element. If it finds the element, it removes the element from the collection using the iterator's remove method.

Note that this implementation throws an `UnsupportedOperationException` if the iterator returned by this collection's iterator method does not implement the remove method and this collection contains the specified object.

**Parameters:**

*value* - element to be removed from this collection, if present

**Returns:**

true if an element was removed as a result of this call

**Exceptions:**

***UnsupportedOperationException*** if the remove operation is not supported by this collection.

                   lang::exceptions::IllegalArgumentException ) [inline, virtual]
```

Removes all of this collection's elements that are also contained in the specified collection (optional operation). After this call returns, this collection will contain no elements in common with the specified collection.

Note that this implementation will throw an **UnsupportedOperationException** if the iterator returned by the iterator method does not implement the remove method and this collection contains one or more elements in common with the specified collection.

**Parameters:**

```

Retains only the elements in this collection that are contained in the specified collection (optional operation). In other words, removes from this collection all of its elements that are not contained in the specified collection.

This implementation iterates over this collection, checking each element returned by the iterator in turn to see if it's contained in the specified collection. If it's not so contained, it's removed from this collection with the iterator's remove method.

Note that this implementation will throw an `UnsupportedOperationException` if the iterator returned by the iterator method does not implement the remove method and this collection contains one or more elements not present in the specified collection.

**Parameters:**

          decaf::lang::exceptions::IllegalMonitorStateException,
          decaf::lang::exceptions::InterruptedException ) [inline, virtual]
```

Waits on a signal from this object, which is generated by a call to Notify. Must have this object locked before calling. This wait will timeout after the specified time interval. This method is similar to the one argument wait function except that it add a finer grained control over the amount of time that it waits by adding in the additional nanosecond argument.

NOTE: The ability to wait accurately at a nanosecond scale depends on the platform and OS that the Decaf API is running on, some systems do not provide an accurate enough clock to provide this level of granularity.

**Parameters:**

*millisecs* the time in milliseconds to wait, or WAIT\_INFINITE

*nanos* additional time in nanoseconds with a range of 0-999999

**Exceptions:**

*IllegalArgumentException* if an error occurs or the nanos argument is not in the range of [0-999999]

*RuntimeException* if an error occurs while waiting on the object.

*InterruptedException* if the wait is interrupted before it completes.

#### 6.2.1 Detailed Description

**template<typename E> class decaf::util::AbstractList< E >**

This class provides a skeletal implementation of the **List** (p. 2337) interface to minimize the effort required to implement this interface backed by a "random access" data store (such as an array). For sequential access data (such as a linked list), **AbstractSequentialList** (p. 198) should be used in preference to this class.

To implement an unmodifiable list, the programmer needs only to extend this class and provide implementations for the `get(int)` and `size()` (p. 1192) methods.

To implement a modifiable list, the programmer must additionally override the `set(int, E)` method (which otherwise throws an `UnsupportedOperationException`). If the list is variable-size the programmer must additionally override the `add(int, E)` and `remove(int)` methods.

The programmer should generally provide a void (no argument) and collection constructor, as per the recommendation in the **Collection** (p. 1184) interface specification.

Unlike the other abstract collection implementations, the programmer does not have to provide an iterator implementation; the iterator and list iterator are implemented by this class, on top of the "random access" methods: `get(int)`, `set(int, E)`, `add(int, E)` and `remove(int)`.

The documentation for each non-abstract method in this class describes its implementation in detail. Each of these methods may be overridden if the collection being implemented admits a more efficient implementation.

#### 6.3.1 Detailed Description

template<typename K, typename V, typename COMPARATOR> class decaf::util::AbstractMap< K, V, COMPARATOR >

This class provides a skeletal implementation of the **Map** (p. 2459) interface, to minimize the effort required to implement this interface. To implement an unmodifiable map, the programmer needs only to extend this class and provide an implementation for the entrySet method, which returns a set-view of the map's mappings. Typically, the returned set will, in turn, be implemented atop **AbstractSet** (p. 199). This set should not support the add or remove methods, and its iterator should not support the remove method.

To implement a modifiable map, the programmer must additionally override this class's put method (which otherwise throws an UnsupportedOperationException), and the iterator returned by entrySet().iterator() must additionally implement its remove method.

The programmer should generally provide a void (no argument) and map constructor, as per the recommendation in the **Map** (p. 2459) interface specification.

The documentation for each non-abstract method in this class describes its implementation in detail. Each of these methods may be overridden if the map being implemented admits a more efficient implementation.

### 6.4.1 Detailed Description

template<typename E> class decaf::util::AbstractQueue< E >

This class provides skeletal implementations of some **Queue** (p. 3149) operations. Methods add, remove, and element are based on offer, poll, and peek, respectively.

A **Queue** (p. 3149) implementation that extends this class must minimally define a method **Queue** (p. 3149). **offer**(E) which does not permit insertion of null elements, along with methods **Queue** (p. 3149). **peek**() (p. 3151), **Queue.poll**() (p. 3151), **Collection.size**() (p. 1192), and a **Collection.iterator**() (p. 2152) supporting **Iterator.remove**() (p. 2155). Typically, additional methods will be overridden as well. If these requirements cannot be met, consider instead subclassing **AbstractCollection** (p. 179).

**6.4.3.1** `template<typename E > virtual bool decaf::util::AbstractQueue< E >::add (const E & value) throw ( decaf::lang::exceptions::UnsupportedOperationException, decaf::lang::exceptions::IllegalArgumentException, decaf::lang::exceptions::IllegalStateException )` [inline, virtual]

Inserts the specified element into this queue if it is possible to do so immediately without violating capacity restrictions, returning true upon success and throwing an `IllegalStateException` if no space is currently available. This implementation returns true if offer succeeds, else throws an `IllegalStateException`.

### Parameters:

*value* - the element to offer to the **Queue** (p. 3149).

### Returns:

true if the add succeeds.

### Exceptions:

*IllegalArgumentException* if the element cannot be added.

Implements `decaf::util::Collection< E >` (p. 1186).

Reimplemented in `decaf::util::PriorityQueue< E >` (p. 3031).

References `decaf::util::Queue< E >::offer()`.

**6.4.3.2** `template<typename E > virtual bool decaf::util::AbstractQueue< E >::addAll (const Collection< E > & collection) throw ( lang::exceptions::UnsupportedOperationException, lang::exceptions::IllegalArgumentException, lang::exceptions::IllegalStateException )` [inline, virtual]

Adds all the elements of a collection to the queue. If the collection is the queue itself, then an `IllegalArgumentException` will be thrown out. If during the process, some runtime exception is thrown out, then part of the elements in the collection that have successfully added will remain in the queue.

The result of the method is undefined if the collection is modified during the process of the method.

### Parameters:

*collection* - the collection to be added to the queue.

**Returns:**

true if the operation succeeds.

**Exceptions:**

***IllegalArgumentException*** If the collection to be added to the queue is the queue itself.

Reimplemented from **decaf::util::AbstractCollection< E >** (p. 183).

**6.4.3.3** `template<typename E > virtual void decaf::util::AbstractQueue< E >::clear  
() throw ( lang::exceptions::UnsupportedOperationException ) [inline,  
virtual]`

Removes all elements of the queue. This implementation repeatedly invokes poll until it returns the empty marker.

Reimplemented from **decaf::util::AbstractCollection< E >** (p. 183).

Reimplemented in **decaf::util::concurrent::SynchronousQueue< E >** (p. 3718), and **decaf::util::PriorityQueue< E >** (p. 3031).

References **decaf::util::AbstractCollection< E >::isEmpty()**, and **decaf::util::Queue< E >::poll()**.

**6.4.3.4** `template<typename E > virtual E decaf::util::AbstractQueue< E >::element  
() const throw ( decaf::lang::exceptions::NoSuchElementException )  
[inline, virtual]`

Retrieves, but does not remove, the head of this queue. This method differs from peek only in that it throws an exception if this queue is empty.

This implementation returns the result of peek unless the queue is empty.

**Returns:**

the element in the head of the queue.

**Exceptions:**

***NoSuchElementException*** if the queue is empty.

Implements **decaf::util::Queue< E >** (p. 3150).

References **decaf::util::Queue< E >::peek()**.

**6.4.3.5** `template<typename E > virtual E decaf::util::AbstractQueue< E >::remove  
() throw ( decaf::lang::exceptions::NoSuchElementException ) [inline,  
virtual]`

Retrieves and removes the head of this queue. This method differs from poll only in that it throws an exception if this queue is empty.

This implementation returns the result of poll unless the queue is empty.

**Returns:**

a copy of the element in the head of the queue.

**Exceptions:**

*NoSuchElementException* if the queue is empty.

Implements **decaf::util::Queue< E >** (p. 3151).

Reimplemented in **decaf::util::PriorityQueue< E >** (p. 3034).

#### 6.5.1 Detailed Description

template<typename E> class decaf::util::AbstractSequentialList< E >

This class provides a skeletal implementation of the **List** (p.2337) interface to minimize the effort required to implement this interface backed by a "sequential access" data store (such as a linked list). For random access data (such as an array), **AbstractList** (p.192) should be used in preference to this class.

This class is the opposite of the **AbstractList** (p.192) class in the sense that it implements the "random access" methods (get(int index), set(int index, E element), add(int index, E element) and remove(int index)) on top of the list's list iterator, instead of the other way around.

To implement a list the programmer needs only to extend this class and provide implementations for the listIterator and size methods. For an unmodifiable list, the programmer need only implement the list iterator's hasNext, next, hasPrevious, previous and index methods.

For a modifiable list the programmer should additionally implement the list iterator's set method. For a variable-size list the programmer should additionally implement the list iterator's remove and add methods.

The programmer should generally provide a void (no argument) and collection constructor, as per the recommendation in the **Collection** (p.1184) interface specification.

```
template<typename E> class decaf::util::AbstractSet< E >
```

This class provides a skeletal implementation of the **Set** (p. 3439) interface to minimize the effort required to implement this interface. The process of implementing a set by extending this class is identical to that of implementing a **Collection** (p.1184) by extending **AbstractCollection** (p.179), except that all of the methods and constructors in subclasses of this class must obey the additional constraints imposed by the **Set** (p. 3439) interface (for instance, the add method must not permit addition of multiple instances of an object to a set).

**6.6.3.1** template<typename E> virtual bool decaf::util::AbstractSet< E >::removeAll (const **Collection**< E > & collection) throw ( lang::exceptions::UnsupportedOperationException, lang::exceptions::IllegalArgumentException ) [inline, virtual]

Removes from this set all of its elements that are contained in the specified collection (optional operation). If the specified collection is also a set, this operation effectively modifies this set so that its value is the asymmetric set difference of the two sets.

This implementation determines which is the smaller of this set and the specified collection, by invoking the size method on each. If this set has fewer elements, then the implementation iterates

over this set, checking each element returned by the iterator in turn to see if it is contained in the specified collection. If it is so contained, it is removed from this set with the iterator's remove method. If the specified collection has fewer elements, then the implementation iterates over the specified collection, removing from this set each element returned by the iterator, using this set's remove method.

Note that this implementation will throw an `UnsupportedOperationException` if the iterator returned by the iterator method does not implement the remove method.

**Parameters:**

*collection* - The **Collection** (p. 1184) whose elements are to be retained

**Returns:**

true if the collection changed as a result of this call

**Exceptions:**

***UnsupportedOperationException***

***IllegalArgumentException***

Reimplemented from **decaf::util::AbstractCollection< E >** (p. 188).

(unsigned char * buffer, int length) const throw (  
cms::MessageEOFException, cms::MessageFormatException,  
cms::MessageNotReadableException, cms::CMSEException ) [virtual]`

Reads a portion of the Stream message stream. If the length of array value is less than the number of bytes remaining to be read from the stream, the array should be filled. A subsequent call reads the next increment, and so on.

If the number of bytes remaining in the stream is less than the length of array value, the bytes should be read into the array. The return value of the total number of bytes read will be less than the length of the array, indicating that there are no more bytes left to be read from the stream. The next read of the stream returns -1.

If length is negative, or length is greater than the length of the array value, then an CMSEException is thrown. No bytes will be read from the stream for this exception case.

**Parameters:**

*buffer* the buffer into which the data is read

*length* the number of bytes to read; must be less than or equal to value.length

### 6.113.1 Detailed Description

Transaction Management class, hold messages that are to be redelivered upon a request to roll-back. The Transaction represents an always running transaction, when it is committed or rolled back it silently creates a new transaction for the next set of messages. The only way to permanently end this transaction is to delete it.

**Since:**

2.0

## 6.114.3 Member Function Documentation

**6.114.3.1** virtual long long decaf::util::zip::Adler32::getValue () const [virtual]

### Returns:

the current checksum value.

Implements **decaf::util::zip::Checksum** (p. 1142).

**6.114.3.2** virtual void decaf::util::zip::Adler32::reset () [virtual]

Reset the checksum to its initial value.

Implements **decaf::util::zip::Checksum** (p. 1143).

**6.114.3.3** virtual void decaf::util::zip::Adler32::update (int *byte*) [virtual]

Updates the current checksum with the specified byte value.

### Parameters:

*byte* The byte value to update the current **Checksum** (p. 1142) with (0..255).

Implements **decaf::util::zip::Checksum** (p. 1143).

**6.114.3.4** virtual void decaf::util::zip::Adler32::update (const unsigned char \* *buffer*, int *size*, int *offset*, int *length*) throw ( decaf::lang::exceptions::NullPointerException, decaf::lang::exceptions::IndexOutOfBoundsException ) [virtual]

Updates the current checksum with the specified array of bytes.

### Parameters:

*buffer* The buffer to read the updated bytes from.

*size* The size of the passed buffer.

*offset* The position in the buffer to start reading.

*length* The amount of data to read from the byte buffer.

### Exceptions:

**NullPointerException** if the passed buffer is NULL.

**IndexOutOfBoundsException** if offset + length > size of the buffer.

Implements **decaf::util::zip::Checksum** (p. 1143).

**6.114.3.5** `virtual void decaf::util::zip::Adler32::update (const std::vector< unsigned char > & buffer, int offset, int length) throw ( decaf::lang::exceptions::IndexOutOfBoundsException )` [virtual]

Updates the current checksum with the specified array of bytes.

**Parameters:**

*buffer* The buffer to read the updated bytes from.

*offset* The position in the buffer to start reading.

*length* The amount of data to read from the byte buffer.

**Exceptions:**

*IndexOutOfBoundsException* if  $\text{offset} + \text{length} > \text{size of the buffer}$ .

Implements `decaf::util::zip::Checksum` (p. 1143).

**6.114.3.6** `virtual void decaf::util::zip::Adler32::update (const std::vector< unsigned char > & buffer)` [virtual]

Updates the current checksum with the specified vector of bytes.

**Parameters:**

*buffer* The buffer to read the updated bytes from.

Implements `decaf::util::zip::Checksum` (p. 1144).
